SUMMARY

Full-stack software engineer with 7+ years in production (Node.js, Angular, TypeScript) who gets hired to make messy processes make sense — for people, and increasingly for the AI models doing the work alongside them. Most of what gets built starts with the same question: what's actually broken here, and what would make it obviously fixed? Lately that question keeps pointing to the same answer: alignment. Not raw code-generation speed, but the trust, verification, and shared understanding that let people and AI models work from the same picture of a problem.

Has been doing pieces of the engineering-leadership job this points toward — designing the operating system a team builds software under, not just individual output within it — before getting a title for it: pushed teams to self-serve through config instead of a developer, owned a customer's trust during a live outage, was the person a team leaned on to keep momentum and process moving. Hasn't managed people directly. Looking for a small team where that operating-system work becomes the explicit job, not a side effect of being senior.

At New Visions, that meant redesigning day-to-day workflow around an AI coding assistant — moving repeatable, model-driven work into deterministic scripts and stored state, and measuring whether each change actually reduced the cost of shipped work, not just felt faster. Separately, building **exec-harness**: not a tool that writes code, but an environment that lets AI agents run unattended and still be trusted — sandboxed verification instead of self-reported outcomes, and an audit trail that can't be quietly rewritten.

That production history (Herff Jones, Marin Software, New Visions) gives the technical half of this — an IC with real architectural credibility, not a title. The other half — clarifying a fuzzy problem until everyone in the room agrees on it before a line of code gets written — comes from performing on Broadway, long before writing a first function.

SKILLS

- **Agent / AI systems:** LLM orchestration, sandboxed/unattended execution, tool-use and context design, agent-harness architecture, verification routing (deterministic checks vs. model judgment)
- **Frontend:** JavaScript, TypeScript, Angular, React, HTML, CSS
- **Backend:** Node.js, Express, NestJS, Java, Redis
- **Database:** MongoDB, Prisma, MySQL, PostgreSQL, Hibernate
- **Infrastructure:** AWS, Docker, Firebase, DigitalOcean, NGINX, CI/CD (Jenkins, GoCD)

EXPERIENCE

Software Engineer Consultant — New Visions for Public Schools

Contract via Summit Staffing Agency | Sep 2025–Present

Full-stack engineer on a multi-tenant student-data platform for a major urban school district — ~100 PRs shipped (85 merged) across ~75 tickets in 10 months, split roughly 60/40 frontend/backend, with strict per-district data isolation enforced throughout.

- Designed and built an electronic parental-consent system end-to-end in about two weeks: researched federal/state e-signature and student-privacy law and the buy-vs-build case, then shipped the consent/signing-token data model, ~15 server routes, and a public signing endpoint that requires no authenticated user yet still enforces per-district isolation by bootstrapping request context from the signed token itself. Added district-scale bulk send and cryptographically signed audit evidence; passed both legal and security-architecture review.
- Owned the platform's largest recent feature end-to-end, a configuration-driven student-profile and demographics system: wrote the technical spec defining the frontend/backend contract, built the shared summary-tile and detail-panel components, and replaced a hard-coded rendering switch with per-district, per-student-type configuration — coordinated as staged handoffs with another engineer against the same contract.
- Made consent status a verified single source of truth across the platform — added a computed field, backfilled it via

migration, and replaced scattered frontend recalculation logic. Separately centralized guardian-record management into a shared service, closing a silent data-correctness gap and fixing a false-match defect in identity resolution.

- Redesigned day-to-day development workflow around an AI coding assistant — replacing conversational, model-driven steps (log analysis, version-control workflows, approval handling) with deterministic scripts and cached state — sustaining a measured, substantial increase in delivered output over multiple months.

Oct 2024–Sep 2025 — independent job search after Marin Software's shutdown; continued self-directed systems work (see Independent Systems Work below).

Software Engineer — Marin Software
Remote | Oct 2022–Oct 2024 (company ceased operations)

Full-stack work on a cross-channel DSP platform integrating third-party ad APIs for campaign management, performance tracking, and data ingestion.

- Built a platform-agnostic JSON-transformation service (NestJS, TypeScript) driven by form-configured rules, cutting code changes for new integrations by 90% and deployments by nearly 100% — let non-engineers manage integrations independently.
- Built middleware to standardize cost/revenue ingestion across ad platforms (Node.js, MongoDB) and internal form-based DSP-onboarding tooling (AngularJS, Node.js), cutting onboarding time by 85%.
- Built and maintained 4 third-party ad-platform API integrations (NestJS, REST, OAuth) for cost/revenue sync and CRUD operations; automated CI/CD workflows with Jenkins, GoCD, and Jest.
- Owned a live customer-facing outage solo during a major customer's go-live: stayed on the call with a pressured stakeholder for about an hour, methodically isolated the fault in the relevant third-party API plugin, and shipped the fix without escalating.

Software Engineer — Herff Jones
Indianapolis, IN (Hybrid) | Jul 2019–Sep 2022

- Resolved 300+ production issues in the first year on a customer-facing legacy platform, stabilizing a critical full-stack system.
- Reverse-engineered and documented an undocumented Java Spring Boot + AngularJS application to onboard the entire team; authored 20+ technical documents and led 7 company-wide presentations.
- Shipped frontend performance work (caching, image rendering and upload optimization) on a student-facing Angular yearbook application at high user scale.

INDEPENDENT SYSTEMS WORK

- **exec-harness** — a queue harness for unattended agent execution: pluggable environment providers, sandboxed "getters" that independently verify agent-produced outcomes rather than trusting self-reports, and immutable sealed attestation as an audit trail.
- **model-recurse** — recursive goal decomposition into a context-threaded tree with Dockerized codegen-and-verify per leaf, applied to a real bank-statement-parsing use case.
- **hub** — a multi-service orchestration system for personal daily use: remote agent-session control, a working voice pipeline, and a Tailscale-exposed catalog of connected apps.

EARLIER EXPERIENCE

Operations Team Lead, Hipstr Photo Activations (Feb–Jul 2019) | Web Developer, Everlasting Wardrobe (May 2018–Feb 2019) | prior career in professional musical theatre (2012–2017).

EDUCATION

BFA in Musical Theatre, University of Michigan. Software development, data structures & algorithms, and applied math coursework through the University of Pennsylvania, University of San Diego, and SkillCrush Coding School.
